I can step through everything just fine until I get to a call

instruction, which doesn't have an explicit base address. In order to compile a program with the knowledge that wherever I'm at in the code, the next address to examine will be at the first byte after that pointer (assuming there's only a single function), I'm using `cdecl`. I've made a small demo program that illustrates this: `$ cat t1203 .globl _start _start: movq $1, %rax movq $0, %rdi movq $0, %rsi xorl $-1, %eax syscall` Here's the assembly: `$ objdump -d t1203 | egrep 'call [0-9a-f]*$' 0000000000400524 : 400524: 55 push %rbp 400525: 48 89 e5 mov %rsp,%rbp 400528: 57`
